

# FluxReader Validation

FluxReader+dk2nu, NovaBeamMat

Erika Cataño Mur

Iowa State University

NOvA Collaboration meeting, October 23, 2014

# Introduction

- ▶ Goals: Check FluxReader outputs, comparing to older scripts; and give a beginner's perspective on user experience

- ▶ Studied flux files in dk2nu format from

`/nusoft/data/flux/dk2nu/nova/2013/flugg_mn000z200i_peanut_lowth/`

- ▶ Compared to results with Ioana's NovaBeamMat (see e.g. [Link1](#) [Link2](#))

`/nova/ana/users/rschroet/flugg_fluxes/flugg_mn000z200i_peanut_lowth/`

- ▶ Histograms generated with same binning; 300 files each; energy spectra normalized to 1/POT

- ▶ POT :

NovaBeamMat: 1.4253 e+08

FluxReader: 1.46806 e +08

- ▶ Thanks to the NOvA Beam group. Special thanks to Ioana and Gareth!

First presentation: [Nova docdb 12091](#)

# Checks

- ✓ Documentation: Tutorial video, Demos, Technical note, Redmine
- ✓ Read 1:1 from dk2nu (new: detector location from dk2nu txt file)
  - ▶ For 1D energy spectra
    - ✓ POT number
    - ✓ Classification by particle type, parent type and sign
    - ✓ Combiner
    - ✓ Cross section applied
    - ✓ No weights, external weights
- ✓ Cross sections
- ✓ pT<sub>pz</sub> 2D histograms

## Section 1

# 2D histograms

# Notes

- ▶ Last time: right-out-of-the-box ptpz distributions with FluxReader /NovaBeamMat looked different
- ▶ One was plotting parent ptpz; the other ancestor ptpz
- ▶ Easy fix in my code. Now everything looks ok.
- ▶ Checked other sources of discrepancy. No bugs to report!
- ▶ Remark: pt/pz variables for ancestors are defined (commented) in FluxReader's Vars.h . Can't use them since this set of dk2nu trees don't have filled the ancestor branch (original Flugg files do have the data).
- ▶ Plotting: pdpt, pdpz: Momentum of the  $\nu$  parent at the  $\nu$  production vertex

# Parent ptpz; NBM (left) FxR (right)

## Section 2

Cross section

# Observation (1)

Notice how the ratio in the 0-0.5 GeV energy range changes after applying cross sections

# Observation (2)

More noticeable for FD since binning is smaller

# Observation (3)

Affects all neutrino types

# Notes

- ▶ Both FluxReader and NovaSoft read the cross section information from a file in \$GENIEXSECPATH (always the most recent version).
- ▶ Graphs appear to be the same

Notice the pretty labels, incl. scale factor :)

# Cross sections and ratios

- ▶ Comparing stored TGraphs. Number of points for a given interval is different → different interpolation; effect more pronounced near 0. Here: linear interpolation
- ▶ Values are usually small. Is this a concern?

## Section 3

## Conclusion

# Conclusion

- ▶ All features compared between FluxReader and NovaBeamMat look fine. FluxReader is more versatile.
- ▶ Package is very user-friendly: code is clean and clear, documentation is outstanding!
- ▶ All issues/ comments have been resolved promptly → kudos!
- ▶ Last suggestions:
  - ▶ `Detector::Print()`
  - ▶ Human-readable units, e.g. Flux in  $\text{Events}/6 \times 10^{20} \text{ POT}/\text{cm}^2/\text{Energy bin}$ , absolute event rate
  - ▶ Simple plotting tools, e.g. Fluxes by neutrino type and total, two types of flux + ratio, FD/ND ratio + double ratio.
- ▶ A comparison for G4NuMi is also a good idea, since the decay chain is coded differently
